Outline

▲ Transport Layer

Transport services and protocols

- ▶ provide *logical communication* between app' processes running on different hosts
- ▶ transport protocols run in end systems
- ▶ **transport vs network layer services:**
 - ▶ *network layer*: data transfer between end systems
 - ▶ *transport layer*: data transfer between processes
 - relies on, enhances, network layer services

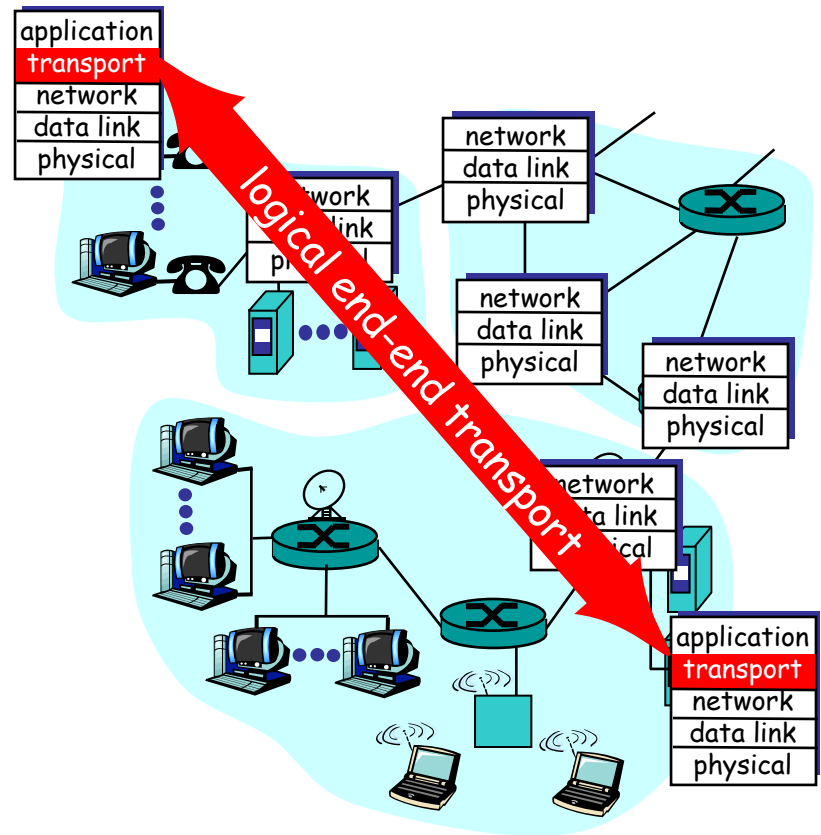

Example

Transport-layer protocols

Internet transport services:

- ▲ reliable, in-order unicast delivery (TCP)
 - congestion
 - flow control
 - connection setup
- ▲ unreliable (“best-effort”), unordered unicast or multicast delivery: UDP
- ▲ services not available:
 - real-time
 - bandwidth guarantees
 - reliable multicast

Multiplexing/demultiplexing

segment - unit of data
exchanged between
transport layer

- aka TPDLL

pro
application
data

Demultiplexing: delivering
segments to
per processes

What is a Socket?

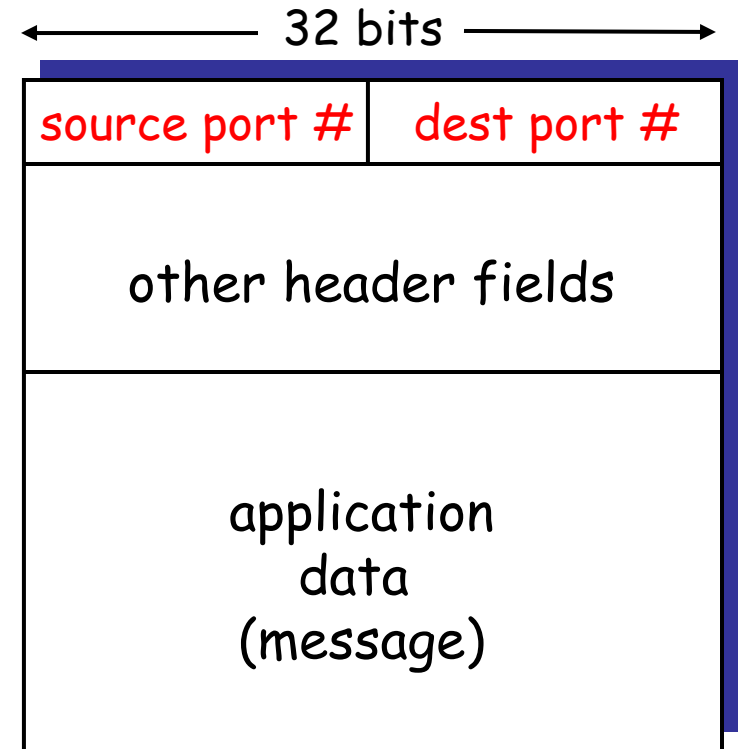

Multiplexing/demultiplexing

Multiplexing:

gathering data from multiple app processes, enveloping data with header (later used for demultiplexing)

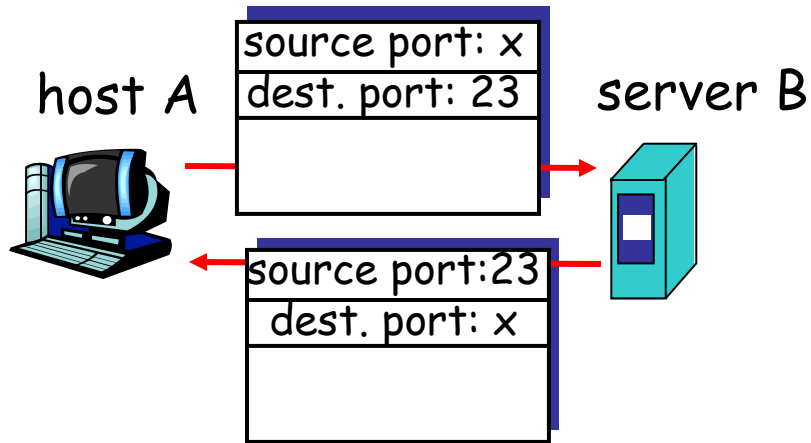

multiplexing/demultiplexing:

- ▲ based on sender, receiver port numbers, IP addresses
 - source, dest port #s in each segment
 - recall: well-known port numbers for specific applications

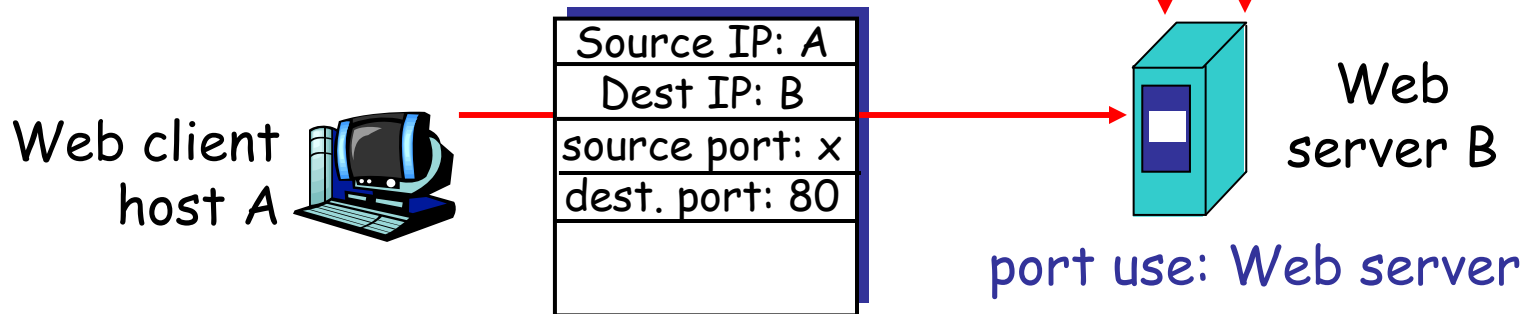

TCP/UDP segment format

Multiplexing/demultiplexing: examples

port use: simple telnet app

UDP: User Datagram Protocol [RFC 768]

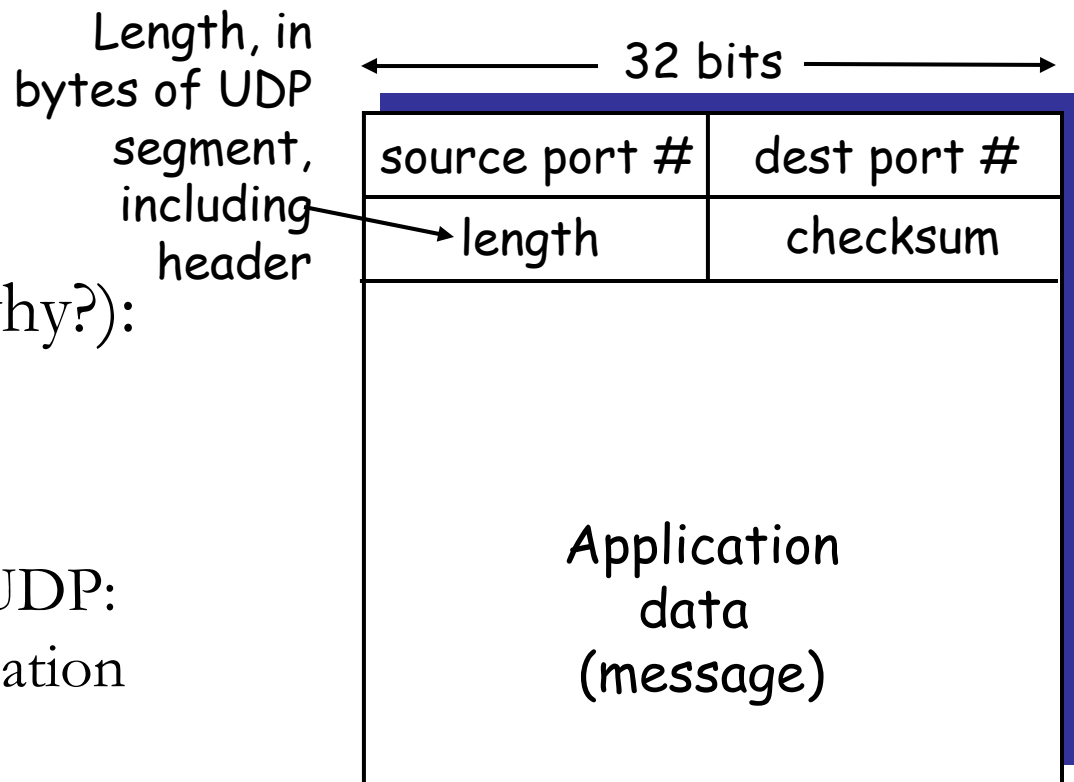

- ▲ “no frills,” “bare bones” Internet transport protocol
- ▲ “best effort” service, UDP segments may be:
 - lost
 - delivered out of order to app
- ▲ *connectionless*:
 - no handshaking between UDP sender, receiver
 - each UDP segment handled independently of others

Why is there a UDP?

- ▲ no connection establishment (which can add delay)
- ▲ simple: no connection state at sender, receiver
- ▲ small segment header
- ▲ no congestion control: UDP can blast away as fast as desired

UDP: more

- ▲ often used for streaming multimedia apps
 - loss tolerant
 - rate sensitive
- ▲ other UDP uses (why?):
 - DNS
 - SNMP
- ▲ reliable transfer over UDP: add reliability at application layer
 - application-specific error recover!

UDP segment format

UDP checksum

Goal: detect “errors” (e.g., flipped bits) in transmitted segment

Sender:

- ▲ treat segment contents as sequence of 16-bit integers
- ▲ checksum: addition (1’s complement sum) of segment contents
- ▲ sender puts checksum value into UDP checksum field

Receiver:

- ▲ compute checksum of received segment
- ▲ check if computed checksum equals checksum field value:
 - NO - error detected
 - YES - no error detected.
But maybe errors nonetheless?

Questions?

That's all for today!
